1 Introduction

Variance-mean mixture distribution

$$Z \sim \mathcal{IG}(\delta\gamma, \gamma^2), \quad X \sim \mathcal{N}(\mu + \beta Z, Z), \quad (1)$$

where $\gamma = \sqrt{\alpha^2 - \beta^2}$. The domain of the parameters is

$$0 \leq |\beta| < \alpha, \quad \mu \in \mathbb{R}, \quad \delta > 0. \quad (2)$$

The density function is given by

$$f(x; \alpha, \beta, \mu, \delta) = \frac{\alpha\delta}{\pi} \frac{K_1\left(\alpha\sqrt{\delta^2 + (x - \mu)^2}\right)}{\sqrt{\delta^2 + (x - \mu)^2}} e^{\delta\gamma + \beta(x - \mu)} \quad (3)$$

The cumulative distribution function is given by

$$F(x; \alpha, \beta, \mu, \delta) = \frac{\alpha\delta e^{\delta\gamma}}{\pi} \int_{-\infty}^x \frac{K_1\left(\alpha\sqrt{\delta^2 + (t - \mu)^2}\right)}{\sqrt{\delta^2 + (t - \mu)^2}} e^{\beta(t - \mu)} dt \quad (4)$$

$$F(x; \alpha, \beta, \mu, \delta) = \frac{\delta}{\sqrt{2\pi}} \int_0^\infty \Phi\left(\frac{x - (\mu + \beta t)}{\sqrt{t}}\right) t^{-3/2} e^{-\frac{(\delta - \gamma t)^2}{2t}} dt \quad (5)$$

Integral representations

Proposition 1.1 *Because $|\beta| < \alpha$, we can write $\beta = \alpha \tanh(\theta)$. Substituting in (4) $x - \mu = \delta \sinh(\theta + u)$ we obtain*

$$F(x; \alpha, \beta, \mu, \delta) = \frac{\alpha\delta e^{\delta\gamma}}{\pi} \int_{-\infty}^\tau K_1(\alpha\delta \cosh(\theta + u)) e^{\beta\delta \sinh(\theta + u)} du, \quad (6)$$

where

$$\tau = \operatorname{arcsinh}\left(\frac{x - \mu}{\delta}\right) - \theta. \quad (7)$$

Standard case $\mu = 0$ and $\delta = 1$

Case $\mu = 0$

Case $\delta = 0$

Case $x = \mu$ If $x = \mu$ and $\beta = 0$ then $F(x; \alpha, 0, \mu, \delta) = \frac{1}{2}$.

2 Preliminaries

In this section, we present some results to be used throughout this work.

2.1 The function $\Phi\left(\frac{a}{\sqrt{t}} + b\sqrt{t}\right)$

The function $F(t; a, b) = \Phi\left(\frac{a}{\sqrt{t}} + b\sqrt{t}\right)$ is part of the integrand of the integral representation in (5). Given its relevance throughout this work, we introduce here some results that shall be used subsequently. $F(t; a, b)$ has the following integral representation [1, §7.7.6]

$$F(t; a, b) = \frac{1}{2} \operatorname{erfc}\left(-\frac{\frac{a}{\sqrt{t}} + b\sqrt{t}}{\sqrt{2}}\right) = \sqrt{\frac{t}{\pi}} e^{-\frac{a^2}{2t}} \int_{-b/\sqrt{2}}^\infty e^{-(tu^2 - \sqrt{2}au)} du \quad (8)$$

2.1.1 Expansion $t \rightarrow 0$

Let us consider the case $a < 0$, since we can use the mirror property $\Phi(z) = 1 - \Phi(-z)$ otherwise. To obtain an expansion for $t \rightarrow 0$, we expand e^{-tu^2} and interchange summation and integration obtaining

$$F(t; a, b) = \sqrt{\frac{t}{\pi}} e^{-\frac{a^2}{2t}} \sum_{k=0}^{\infty} \frac{(-t)^k}{k!} \int_{-b/\sqrt{2}}^{\infty} e^{\sqrt{2}au} u^{2k} du.$$

For $a < 0$ the integral can be expressed in closed-form in terms of the incomplete gamma function, $\Gamma(a, x)$

$$\int_{-b/\sqrt{2}}^{\infty} e^{\sqrt{2}au} u^{2k} du = \frac{\Gamma(2k+1, -ab)}{(\sqrt{2}a)^{2k+1}},$$

and for the special case $b = 0$, it reduces to

$$\int_0^{\infty} e^{\sqrt{2}au} u^{2k} du = \frac{\Gamma(2k+1)}{(\sqrt{2}a)^{2k+1}}.$$

Then, we obtain the series expansion valid for $t \rightarrow 0$, $a \rightarrow -\infty$ and fixed b

$$F(t; a, b) = \sqrt{\frac{t}{\pi}} e^{-\frac{a^2}{2t}} \sum_{k=0}^{\infty} \frac{(-1)^{k+1} t^k}{k!} \frac{\Gamma(2k+1, ab)}{(\sqrt{2}a)^{2k+1}}. \quad (9)$$

Moreover, another expansion valid for large values of $a > 0$ and b can be obtained after expanding $F(t; a, b)$ at $t = 0$. The first coefficients are

$$c_0 = \frac{1}{a}, \quad c_1 = \frac{ab+1}{a^3}, \quad c_2 = \frac{a^2b+3ab+3}{a^5}, \quad c_3 = \frac{a^3b^3+6a^2b^3+15ab+15}{a^7} \quad (10)$$

and the expansion reads

$$F(t; a, b) = 1 + \frac{e^{-\frac{1}{2}\left(\frac{a}{\sqrt{t}}+b\sqrt{t}\right)^2}}{\sqrt{2\pi}} \sum_{k=0}^{\infty} (-1)^{k+1} c_k t^{k+\frac{1}{2}}. \quad (11)$$

The coefficients are expressible in terms of Bessel polynomials $y_k(x)$ [2, §A001498], and it follows that

$$F(t; a, b) = 1 + \frac{e^{-\frac{1}{2}\left(\frac{a}{\sqrt{t}}+b\sqrt{t}\right)^2}}{a\sqrt{2\pi}} \sum_{k=0}^{\infty} (-1)^{k+1} \left(\frac{b}{a}\right)^k y_k\left(\frac{1}{ab}\right) t^{k+\frac{1}{2}}, \quad (12)$$

where $y_k(x)$ has an explicit formula

$$y_k(x) = \sum_{m=0}^k \binom{k}{m} (k+1)_m \left(\frac{x}{2}\right)^m. \quad (13)$$

Using the connection of the Bessel polynomials with the modified Bessel function of the second kind $K_k(x)$ given by [3, §33.1.3]

$$y_k(x) = \sqrt{\frac{2}{\pi x}} e^{1/x} K_{k+\frac{1}{2}}\left(\frac{1}{x}\right), \quad (14)$$

the resulting expansion is represented as a Bessel-type expansion

$$F(t; a, b) = 1 + \frac{e^{-\frac{a^2}{2t}-\frac{b^2}{2}t}}{\pi} \sqrt{\frac{b}{a}} \sum_{k=0}^{\infty} (-1)^{k+1} \left(\frac{b}{a}\right)^k K_{k+\frac{1}{2}}(ab) t^{k+\frac{1}{2}}. \quad (15)$$

The expansion is convergent for $t < 1$. The convergence follows from the asymptotic estimate of $(b/a)^k K_k(ab) \sim (b/a)^k \sqrt{\frac{\pi}{2ab}} e^{-ab}$ as $|ab| \rightarrow \infty$. The expansion can be seen as an asymptotic expansion for large a , or as a uniform asymptotic expansion for $a \sim b$. The coefficients can be computed by using a recurrence relation for the modified Bessel function.

2.1.2 Expansion $t \rightarrow \infty$

Let us focus on the case $t \rightarrow \infty$. We can develop an asymptotic expansion after expanding the term $e^{\sqrt{2}au}$ in (8), which yields

$$F(t; a, b) = \sqrt{\frac{t}{\pi}} e^{-\frac{a^2}{2t}} \sum_{k=0}^{\infty} \frac{(\sqrt{2}a)^k}{k!} \int_{-b/\sqrt{2}}^{\infty} e^{-tu^2} u^k du.$$

Considering the case $b < 0$ (again, we can use the mirror property), the integral has a closed-form

$$\int_{-b/\sqrt{2}}^{\infty} e^{-tu^2} u^k du = \frac{\Gamma\left(\frac{k+1}{2}, \frac{b^2}{2}t\right)}{2t^{\frac{k+1}{2}}}.$$

Thus,

$$F(t; a, b) = \sqrt{\frac{t}{\pi}} \frac{e^{-\frac{a^2}{2t}}}{2} \sum_{k=0}^{\infty} \frac{(\sqrt{2}a)^k}{k!} \frac{\Gamma\left(\frac{k+1}{2}, \frac{b^2}{2}t\right)}{t^{\frac{k+1}{2}}}. \quad (16)$$

The asymptotic behaviour of the terms in the series is

$$\frac{\Gamma\left(\frac{k+1}{2}, \frac{b^2}{2}t\right)}{t^{\frac{k+1}{2}}} \sim \left(\frac{b^2}{2}\right)^{\frac{k+1}{2}} e^{-\frac{b^2}{2}t}, \quad t \rightarrow \infty.$$

In fact this series is convergent, as can be observed taking the asymptotic estimate of $\Gamma(k, x)$ as $k \rightarrow \infty$. A simpler convergent expansion can be obtained transforming the integral in (8)

$$\sqrt{\frac{t}{\pi}} e^{-\frac{a^2}{2t}} \int_{-b/\sqrt{2}}^{\infty} e^{-(tu^2 - \sqrt{2}au)} du = \sqrt{\frac{t}{\pi}} e^{-\frac{a^2}{2t} - ab - \frac{b^2}{2}t} \int_0^{\infty} e^{\sqrt{2}(a+bt)u} e^{-tu^2} dt,$$

and expanding $e^{\sqrt{2}(a+bt)u}$ obtaining

$$F(t; a, b) = \sqrt{\frac{t}{\pi}} \frac{e^{-\frac{a^2}{2t} - ab - \frac{b^2}{2}t}}{2} \sum_{k=0}^{\infty} \frac{(\sqrt{2}(a+bt))^k}{k!} \frac{\Gamma\left(\frac{k+1}{2}\right)}{t^{\frac{k+1}{2}}}. \quad (17)$$

Similarly to the expansion at $t \rightarrow 0$, we can obtain an asymptotic expansion expanding $F(t; a, b)$ at $t \rightarrow \infty$. For $b > 0$, the first terms of the expansion are

$$c_0 = 1, \quad c_1 = 2 + 2ab + a^2b^2, \quad c_2 = 24 + 24ab + 12a^2b^2 + 4a^3b^3 + a^4b^4, \quad (18)$$

$$F(t; a, b) = 1 + \frac{e^{-ab - \frac{b^2}{2}t}}{\sqrt{2\pi}} \sum_{k=0}^{\infty} \frac{(-1)^{k+1}}{2^k k!} \frac{c_k}{b^{2k+1}} \left(\frac{1}{t}\right)^{k+\frac{1}{2}}. \quad (19)$$

The coefficients c_k are expressible in terms of the incomplete gamma function, since

$$c_k = \sum_{j=0}^{2k} \frac{(2k)!}{j!} (ab)^j = e^{ab} \Gamma(2k+1, ab).$$

Rearranging terms, we get

$$F(t; a, b) = 1 + \frac{e^{-\frac{b^2}{2}t}}{\sqrt{2\pi}} \sum_{k=0}^{\infty} \frac{(-1)^{k+1}}{2^k k!} \frac{\Gamma(2k+1, ab)}{b^{2k+1}} \left(\frac{1}{t}\right)^{k+\frac{1}{2}}. \quad (20)$$

2.1.3 Expansion $t \rightarrow u$

Lastly, we study the expansion of $F(t; a, b)$ at $t = u$. This expansion shall be crucial when developing various Bessel-type asymptotic expansions later on. The first coefficients of the Taylor series are

$$c_0 = \Phi\left(\frac{a}{\sqrt{u}} + b\sqrt{u}\right) d_0, \quad c_1 = \phi\left(\frac{a}{\sqrt{u}} + b\sqrt{u}\right) d_1, \quad c_2 = -\phi\left(\frac{a}{\sqrt{u}} + b\sqrt{u}\right) d_2, \quad c_3 = \phi\left(\frac{a}{\sqrt{u}} + b\sqrt{u}\right) d_3,$$

where

$$\begin{aligned} d_0 &= 1 \\ d_1 &= \frac{-a + bu}{2u^{3/2}} \\ d_2 &= \frac{a^3 - 3au - a^2bu + bu^2 - ab^2u^2 + b^3u^3}{8u^{7/2}} \\ d_3 &= \frac{-a^5 + 10a^3u + a^4bu - 15au^2 - 6a^2bu^2 + 2a^3b^2u^2 + 3bu^3 - 6ab^2u^3 - 2a^2b^3u^3 + 2b^3u^4 - ab^4u^4 + b^5u^5}{48u^{11/2}}, \end{aligned}$$

and $\phi(x) = \frac{e^{-x^2/2}}{\sqrt{2\pi}}$ is the probability density function of the standard normal distribution. Thus, we have

$$F(t; a, b) = \sum_{k=0}^{\infty} c_k(t-u)^k. \quad (21)$$

Additional terms satisfy the following recurrence

$$c_{k+4} = \frac{f_0(k)c_k + f_1(k)c_{k+1} + f_2(k)c_{k+2} + f_3(k)c_{k+3}}{f_4(k)}, \quad k \geq 0 \quad (22)$$

where

$$\begin{aligned} f_0(k) &= -kb^3 \\ f_1(k) &= -(1+k)b(1+2k-ab+3b^3u) \\ f_2(k) &= (2+k)(5a+2ka+a^2b-8bu-6kbu+2ab^2u-3b^3u^2) \\ f_3(k) &= -(3+k)(a^3-11au-4kau-a^2bu+13bu^2+6kbu^2-ab^2u^2+b^3u^3) \\ f_4(k) &= 2(3+k)(4+k)u^2(-a+bu) \end{aligned}$$

2.2 Bessel-type expansions

3 Methods of computation

3.1 Expansions $|x - \mu| \rightarrow 0$

The starting point is the integral representation in (5) after expanding the exponential

$$F(x; \alpha, \beta, \mu, \delta) = \frac{\delta e^{\delta\gamma}}{\sqrt{2\pi}} \int_0^\infty \Phi\left(\frac{x - (\mu + \beta t)}{\sqrt{t}}\right) t^{-3/2} e^{-\frac{\delta^2}{2t} - \frac{\gamma^2}{2}t} dt,$$

and replacing $\Phi\left(\frac{x - (\mu + \beta t)}{\sqrt{t}}\right)$ by the expansion in (16)

$$F(x; \alpha, \beta, \mu, \delta) = \frac{\delta e^{\delta\gamma}}{\sqrt{2\pi}} \sum_{k=0}^{\infty} \frac{2^{k/2}(x - \mu)^k}{k!} \int_0^\infty \Gamma\left(\frac{k+1}{2}, \frac{\beta^2}{2}t\right) t^{-3/2-k/2} e^{-\frac{\omega^2}{2t} - \frac{\gamma^2}{2}t} dt,$$

where $\omega = \sqrt{\delta^2 + (x - \mu)^2}$. Consider the ascending series of the incomplete gamma function given by [1, §8.7]

$$\Gamma(a, x) = \Gamma(a) - \sum_{j=0}^{\infty} \frac{(-1)^j x^{a+j}}{j!(a+j)}. \quad (23)$$

We proceed splitting the inner integral into two terms

$$T_1 = \Gamma\left(\frac{k+1}{2}\right) \int_0^\infty t^{-3/2-k/2} e^{-\frac{\omega^2}{2t} - \frac{\gamma^2}{2}t} dt \quad (24)$$

$$T_2 = \sum_{j=0}^{\infty} \frac{(-1)^j \left(\frac{\beta^2}{2}\right)^{\frac{k+1}{2}+j}}{j! \left(\frac{k+1}{2} + j\right)} \int_0^\infty t^{j-1} e^{-\frac{\omega^2}{2t} - \frac{\gamma^2}{2}t} dt, \quad (25)$$

and observe that both integrals are expressible in terms of modified Bessel function, resulting in the sums S_1 and S_2 , such that $F(x; \alpha, \beta, \mu, \delta) = C(S_1 - S_2)$, defined as follows

$$S_1 = \sum_{k=0}^{\infty} \frac{2^{k/2}(x-\mu)^k}{k!} \Gamma\left(\frac{k+1}{2}\right) 2K_{\frac{k+1}{2}}(\omega\gamma) \left(\frac{\gamma}{\omega}\right)^{\frac{k+1}{2}} \quad (26)$$

$$S_2 = \sum_{k=0}^{\infty} \frac{2^{k/2}(x-\mu)^k}{k!} \sum_{j=0}^{\infty} \frac{(-1)^j \left(\frac{\beta^2}{2}\right)^{\frac{k+1}{2}+j}}{j! \left(\frac{k+1}{2} + j\right)} 2K_j(\omega\gamma) \left(\frac{\omega}{\gamma}\right)^j. \quad (27)$$

Interchanging the order of summation in S_2 , we observe that the sum in k is convergent and expressible in terms of the lower incomplete gamma function $\gamma(a, x)$. Assuming $\beta > 0$

$$\sum_{k=0}^{\infty} \frac{2^{k/2}(x-\mu)^k}{k! \left(\frac{k+1}{2} + j\right)} \left(\frac{\beta^2}{2}\right)^{\frac{k+1}{2}} = -\frac{\sqrt{2}}{(x-\mu)^{2j+1} \beta^{2j}} \gamma(2j+1, -(x-\mu)\beta). \quad (28)$$

Thus,

$$S_2 = -2\sqrt{2} \sum_{j=0}^{\infty} \frac{(-1)^j}{j!} \frac{\gamma(2j+1, -(x-\mu)\beta)}{(x-\mu)^{2j+1} \beta^{2j}} \left(\frac{\beta^2}{2}\right)^j K_j(\omega\gamma) \left(\frac{\omega}{\gamma}\right)^j$$

Rearranging terms

$$F(x; \alpha, \beta, \mu, \delta) = \frac{\delta e^{\delta\gamma}}{\pi\sqrt{2}} \left[\sum_{k=0}^{\infty} \frac{2^{k/2}(x-\mu)^k}{k!} \Gamma\left(\frac{k+1}{2}\right) K_{\frac{k+1}{2}}(\omega\gamma) \left(\frac{\gamma}{\omega}\right)^{\frac{k+1}{2}} + \sqrt{2} \sum_{k=0}^{\infty} \frac{(-1)^k}{k!} \frac{\gamma(2k+1, -(x-\mu)\beta)}{(x-\mu)^{2k+1} \beta^{2k}} K_k(\omega\gamma) \left(\frac{\omega}{2\gamma}\right)^k \right] \quad (29)$$

If $\beta < 0$ then $F(x; \alpha, \beta, \mu, \delta) = 1 - F(-x; \alpha, -\beta, -\mu, \delta)$. The expansion is convergent for small $x - \mu$ and fixed values of the rest of parameters. Moreover, the convergence improves when $\gamma \sim \omega$, also valid for large values for these two parameters.

3.1.1 Case $\delta \rightarrow \infty$

3.1.2 Special value $\beta = 0$

We use the integral (5). For $|x - \mu| \rightarrow 0$, we use the series expansion of $\Phi(x)$ given by

$$\Phi(x) = \frac{1}{2} + \frac{1}{\sqrt{2\pi}} \sum_{k=0}^{\infty} \frac{(-1)^k x^{2k+1}}{2^k k! (2k+1)}$$

$$\Phi(x) = \frac{1}{2} + \frac{e^{-x^2/2}}{\sqrt{2\pi}} \sum_{k=0}^{\infty} \frac{x^{2k+1}}{(2k+1)!!}$$

Use closed-form in terms of the modified Bessel function. Alternating series

$$F(x; \alpha, 0, \mu, \delta) = \frac{1}{2} + \frac{\delta e^{\delta\gamma}}{\pi} \sum_{k=0}^{\infty} \frac{(-1)^k (x-\mu)^{2k+1}}{2^k k! (2k+1)} \left(\frac{\alpha}{\delta}\right)^{k+1} K_{k+1}(\alpha\delta). \quad (30)$$

Asymptotic analysis of $K_{k+1}(\alpha\delta)$. To obtain a series with positive term for $x - \mu > 0$, use alternative expansion of $\Phi(x)$

$$F(x; \alpha, 0, \mu, \delta) = \frac{1}{2} + \frac{\delta e^{\delta\gamma}}{\pi} \sum_{k=0}^{\infty} \frac{(x-\mu)^{2k+1}}{(2k+1)!!} \left(\frac{\alpha}{\omega}\right)^{k+1} K_{k+1}(\alpha\omega), \quad \omega = \sqrt{\delta^2 + (x-\mu)^2}. \quad (31)$$

3.2 Expansion $\alpha \rightarrow \infty, \delta \rightarrow \infty$

3.3 Expansion $|x - \mu| \rightarrow \infty$

The expansion of $\Phi\left(\frac{x-(\mu+\beta t)}{\sqrt{t}}\right)$ at $t \rightarrow 0$ is given in terms of the Bessel polynomial $y_k(x)$. To simplify notation, we take $a = x - \mu$ and $b = -\beta$. Then,

$$\Phi\left(\frac{a}{\sqrt{t}} + b\sqrt{t}\right) = 1 + \frac{e^{-a^2/(2t) - ab - b^2/2t}}{a\sqrt{2\pi}} \sum_{k=0}^{\infty} (-1)^{k+1} \left(\frac{b}{a}\right)^k y_k\left(\frac{1}{ab}\right) t^{\frac{1}{2}+k} \quad (32)$$

Using the connection of the Bessel polynomials with the modified Bessel function of the second kind $K_n(x)$ given by

$$y_n(x) = \sqrt{\frac{2}{\pi x}} e^{1/x} K_{n+\frac{1}{2}}\left(\frac{1}{x}\right), \quad (33)$$

we replace in the integral, we obtain

$$F(x; \alpha, \beta, \mu, \delta) = 1 + \delta e^{\delta\gamma} \sqrt{\frac{b}{2a\pi^3}} \sum_{k=0}^{\infty} (-1)^{k+1} \left(\frac{b}{a}\right)^k K_{k+\frac{1}{2}}(ab) \int_0^{\infty} t^{k-1} e^{-\frac{\delta^2+a^2}{2t} - \frac{\gamma^2+b^2}{2}t} dt \quad (34)$$

$$\int_0^{\infty} t^{k-1} e^{-\frac{\delta^2+a^2}{2t} - \frac{\gamma^2+b^2}{2}t} dt = 2K_k(\omega\alpha) \left(\frac{\omega}{\alpha}\right)^k, \quad (35)$$

where $\omega = \sqrt{\delta^2 + (x - \mu)^2}$. Rearranging terms

$$F(x; \alpha, \beta, \mu, \delta) = 1 + \delta e^{\delta\gamma} \sqrt{\frac{2\beta}{(\mu - x)\pi^3}} \sum_{k=0}^{\infty} (-1)^{k+1} \left(\frac{\beta\omega}{\alpha(\mu - x)}\right)^k K_{k+\frac{1}{2}}((\mu - x)\beta) K_k(\omega\alpha) \quad (36)$$

3.3.1 Special value $\beta = 0$

For $x - \mu < 0$

$$F(x; \alpha, 0, \mu, \delta) = \frac{\delta e^{\delta\alpha}}{\pi} \sum_{k=0}^{\infty} \frac{(-1)^{k+1} \Gamma(2k+1)}{2^k k! (x - \mu)^{2k+1}} \left(\frac{\omega}{\alpha}\right)^k K_k(\alpha\omega), \quad \omega = \sqrt{(x - \mu)^2 + \delta^2}. \quad (37)$$

4 Other expansions

Proposition 4.1 For $x - \mu < 0$

$$F(x; \alpha, \beta, \mu, \delta) = \frac{\sqrt{2}\delta e^{\delta\gamma}}{\pi} \int_{\beta/\sqrt{2}}^{\infty} e^{\sqrt{2}(x-\mu)t} K_0\left(\sqrt{2((x-\mu)^2 + \delta^2)} \sqrt{\frac{\gamma^2}{2} + t^2}\right) dt \quad (38)$$

Proof: Consider the integral representation of the function $\Phi\left(\frac{x-\mu}{\sqrt{t}} - \beta\sqrt{t}\right)$

$$\Phi\left(\frac{x-\mu}{\sqrt{t}} - \beta\sqrt{t}\right) = \sqrt{\frac{t}{\pi}} e^{-\frac{(x-\mu)^2}{2t}} \int_{\beta/\sqrt{2}}^{\infty} e^{-(tu^2 - \sqrt{2}(x-\mu)u)} du.$$

Replacing in (5) and interchanging the order of integration we obtain

$$F(x; \alpha, \beta, \mu, \delta) = \frac{\delta e^{\delta\gamma}}{\sqrt{2}\pi} \int_{\beta/\sqrt{2}}^{\infty} e^{\sqrt{2}(x-\mu)u} \int_0^{\infty} t^{-1} e^{-\frac{(x-\mu)^2 + \delta^2}{2t} - \left(\frac{\gamma^2}{2} + u^2\right)t} dt du.$$

The observation that the inner integral can be represented in terms of the modified Bessel function K_0

$$\int_0^{\infty} t^{-1} e^{-\frac{(x-\mu)^2 + \delta^2}{2t} - \left(\frac{\gamma^2}{2} + u^2\right)t} dt = 2K_0\left(2\sqrt{\frac{(x-\mu)^2 + \delta^2}{2}} \sqrt{\frac{\gamma^2}{2} + u^2}\right).$$

□

A similar expansion can be obtained from the integral representation (38), expanding $e^{\sqrt{2}(x-\mu)t}$

$$e^{\sqrt{2}(x-\mu)t} = \sum_{k=0}^{\infty} \frac{2^{k/2}(x-\mu)^k}{k!} t^k$$

$$F(x; \alpha, 0, \mu, \delta) = \frac{\sqrt{2}\delta e^{\delta\gamma}}{\pi} \sum_{k=0}^{\infty} \frac{2^{k/2}(x-\mu)^k}{k!} \int_0^{\infty} t^k K_0 \left(\sqrt{2((x-\mu)^2 + \delta^2)} \sqrt{\frac{\gamma^2}{2} + t^2} \right) dt$$

Use closed-form in terms of the modified Bessel function

$$F(x; \alpha, 0, \mu, \delta) = \frac{\delta e^{\delta\gamma}}{2\pi} \sum_{k=0}^{\infty} \frac{(x-\mu)^k}{2^{k/2}\Gamma(\frac{k}{2} + 1)} \left(\frac{\alpha}{\omega} \right)^{\frac{k+1}{2}} K_{\frac{k+1}{2}}(\omega\alpha), \quad \omega = \sqrt{\delta^2 + (x-\mu)^2}. \quad (39)$$
